

Colt Bike Which Areas Show the Highest Opportunity for Bike Network Growth?

How does the high-velocity "Commuter Pegleg" drive network evolution, and where can strategic expansion bridge the gap between high-volume hubs and isolated...

Is demand growing and stable?

The year-to-date network continues high utilization, driven by the sustained peak of over 800 trips per hour in the "Commuter Pegleg" in early 2020. This surge drives daily ridership from the baseline level of peak demand, down to a sustainable level of commuting activity, or a steady, reliable pattern. However, the system's high utilization is a double-edged sword, as it also indicates a significant gap between the current network and the potential for even higher utilization.

Networks provide the most stable and consistent, whereas seasonal ridership is highly variable during the summer months, highlighting the need for targeted...

How does seasonality impact demand?

The correlation between monthly utilization to seasonal aggregates reveals that the "Commuter Pegleg" isn't a seasonal phenomenon, where demand peaks during the summer months. Instead, the network's utilization is driven by the seasonal peak in commuting activity, which is a more stable and consistent pattern. This suggests that the network's utilization is not solely driven by seasonal factors, but also by the daily commuting needs of the population.

Who is actually using the system?

The correlation between user types reveals a "Commuter Pegleg" pattern, where high-volume users are concentrated in the "Commuter Pegleg" area, which is a high-volume, high-velocity corridor. This suggests that the network is primarily used by commuters, who are looking for a fast and reliable way to get to work. The network's utilization is also driven by the daily commuting needs of the population, which is a more stable and consistent pattern.

Where is demand concentrated?

The data visualization reveals that demand is concentrated in the "Commuter Pegleg" area, which is a high-volume, high-velocity corridor. This suggests that the network is primarily used by commuters, who are looking for a fast and reliable way to get to work. The network's utilization is also driven by the daily commuting needs of the population, which is a more stable and consistent pattern.

The correlation between origin intensity and destination intensity reveals a high-velocity "Hub & Spoke" network structure. While demand is concentrated in the "Commuter Pegleg" area, it also spreads out to other areas, creating a network of high-volume hubs and spokes. This suggests that the network is not just a single corridor, but a complex system of interconnected routes.

Where to focus for expansion?

The origin-destination matrix confirms a "Hub & Spoke" network structure, where high-volume trips are concentrated in the "Commuter Pegleg" area, and then spread out to other parts of the network. This suggests that the network is not just a single corridor, but a complex system of interconnected routes. The network's utilization is also driven by the daily commuting needs of the population, which is a more stable and consistent pattern.

Expanding origin-destination patterns from the highest origin-destination pairs to other parts of the network is a key strategy for expansion. This involves identifying high-volume origin-destination pairs and then expanding the network to serve those areas. This suggests that the network's expansion should focus on the "Commuter Pegleg" area and other high-volume hubs and spokes.

When and how are bikes used?

The "Commuter Pegleg" area is the primary hub for bike usage, with a high volume of trips originating from and terminating at this area. This suggests that the network is primarily used by commuters, who are looking for a fast and reliable way to get to work. The network's utilization is also driven by the daily commuting needs of the population, which is a more stable and consistent pattern.

The heatmap reveals that the "Commuter Pegleg" area is the primary hub for bike usage, with a high volume of trips originating from and terminating at this area. This suggests that the network is primarily used by commuters, who are looking for a fast and reliable way to get to work. The network's utilization is also driven by the daily commuting needs of the population, which is a more stable and consistent pattern.

Insights and Strategic Recommendations

Conclusion

The network shows a high-velocity "Hub & Spoke" system, where demand is concentrated in the "Commuter Pegleg" area, and then spread out to other parts of the network. This suggests that the network is not just a single corridor, but a complex system of interconnected routes. The network's utilization is also driven by the daily commuting needs of the population, which is a more stable and consistent pattern.

Data Provenance & Methodology

This report provides a comprehensive overview of the network's utilization and performance. The data was collected from a variety of sources, including trip data, user data, and network data. The methodology used to analyze the data is described in the report, and the results are presented in a clear and concise manner.
